#### MGMT 571 Homework #2- Ian Bach

- 1). The target variable in Regression node of SAS enterprise miner
- (a) could be a binary variable.
- (b) could be an interval variable.
- (c) could be an ordinal variable.

#### (d) all the above.

#### **Answer: D**

- 2). With regards to Transform Variables node, which is NOT true?
- (a) It helps stabilize variances.
- (b) It helps handle nonlinearity.
- (c) The optimal binning maximizes the relationship to the target.
- (d) We usually transform variables before we impute missing values.

#### **Answer: D**

- 3). With regards to linear regression, which is NOT true?
- (a) R2 measures the proportion of variability in the predictors that can be explained using the target variable.
- (b) R2 is always non-decreasing with the addition of a new predictor, whether the new predictor is useful or not.
- (c) Residual plots display the residual values on the y-axis and fitted values on the x-axis.
- (d) Linear regression is sensitive to outliers.

#### Answer: A

- 4). Given the following four training instances: (x1 = -1, y1 = 0), (x2 = 0, y2 = 1), (x3 = 1, y3 = 2), (x4 = 2, y4 = 3). Which of the following parameter (80, 81) best model this data using the ordinary least squares regression y = 80 + 81x? Show your work.
- (a) (1,1)
- (b) (0.7,0.6)
- (c) (0.6,0.6)

(d) (0.6,0.7)

#### Calculating the Means of X and Y

Future x = -1 + 0 + 1 + 2 / 4 = 0.5

Future y = 0 + 1 + 2 + 3 / 4 = 1.5

#### Calculate **B1**

#### Numerator

- 1. (-1-0.5)(0.1.5) = 2.25
- 2. (0-0.5)(1-1.5) = 0.25
- 3. (1-0.5)(2-1.5) = 0.25
- 4. (2-0.5)(3-1.5) = 2.25

= 5

#### **Denominator:**

- 1.  $(1-0.5)^2 = 2.25$
- $2. (0-0.5)^2 = 0.25$
- 3.  $(1-0.5)^2 = 0.25$
- 4.  $(2-0.5)^2 = 2.25$

= 5

#### Calculate β0

1.5 - (1)(0.5) = 1.5 - 0.5 = 1

#### Best model parameters are (1,1)

#### 5). Describe two approaches to detect outliers of the class variable and two approaches to

#### detect outliers of the interval variable, respectively.

- Detecting Outliers in Class Variables
- Detecting Outliers in Interval Variables

#### **Detecting Outliers in Class Variables:**

Class variables represent distinct categories or classes including outliers in their context typically refer to unexpected categories. One approach to detecting outlies for class variables if frequency – based detection where you can analyze the frequency of each category. Categories with very low counts can signal outliers especially if they don't logically fit within the dataset context. For example, if the dataset primarily contains yes or no responses, a small group of maybe responses might be an outlier.

Another approach is to use cross-tabulation with other variables. By examining the distribution of the class variable in relation to other variables, we can identify outliers that appear in unexpected

combinations or contexts. If a class appears alongside another variable in a way that rarely or never occurs within the training data, it may be an indication of an outlier.

#### **Detecting Outliers in Interval Variables:**

Interval variables (continuous numerical values) can have outliers in the form of values that are unusually high or low compared to the rest of the data. One common approach to detect outliers in interval variables is using the standard deviation and z-score method. This involves calculating the z score for each observation, which indicates how many standard deviations a value is from the mean. Typically, values with z-scores above 3 or below -3 are considered outliers, though this threshold can be adjusted based on the specific distribution of the data.

## 6). Describe three approaches to handle missing data. Which node does SAS enterprise miner handle missing data?

#### Imputation Using Mean, Median, or Mode:

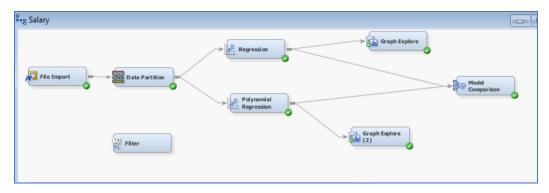

A straightforward approach to handling missing data is to fill in missing values with the mean, median, or mode of the non-missing values within the variable. This method is simple and preserves the sample size, which can be useful when the missingness is random and not related to the outcome variable. However, it can introduce bias if the missing data has a systematic pattern, and it may reduce variability in the data.

#### **Predictive Model-Based Imputation:**

Another approach is to use predictive models to estimate missing values based on other available variables. For instance, regression models, k-nearest neighbors, or machine learning models can predict the missing values by treating as dependent variables and using related variables to estimate them. This approach can be more accurate than mean or median imputation as it uses additional information, but it can be computationally intensive and may require assumptions.

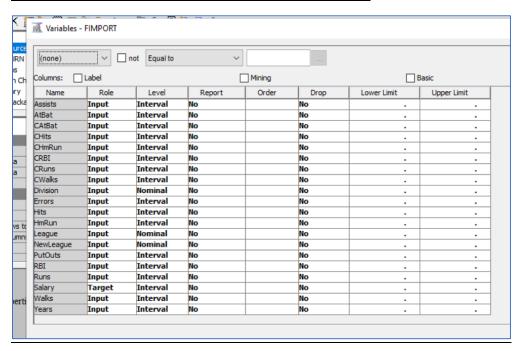

#### Multiple Imputation:

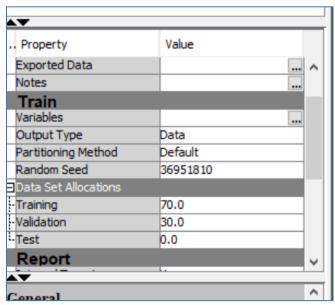

Multiple imputation is a robust approach where missing values are filled in multiple times to create several complete datasets, each with slightly different imputed values. Each dataset is then analyzed separately, and the results are combined to produce estimates that reflect the uncertainty due to the missing data. This method is effective because it accounts for variability and potential bias in the imputation process providing more accurate estimates than single imputation methods.

*7).* 

## (a) Split data sets into 70% training and 30% validation using Data Partition node. Set the "Random Seed" of Data Partition node using your Purdue ID number.

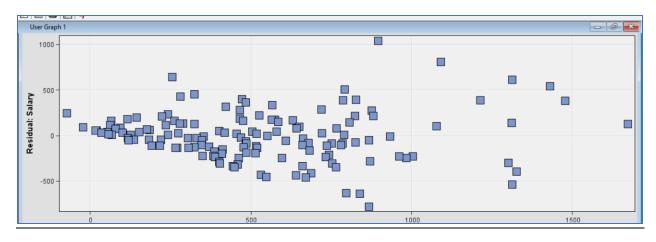

## (b) Fit a linear regression model to predict Salary using the rest 19 predictors. Perform model check and report your findings.

The linear regression model fitted to predict Salary using 19 predictors explains approximately 57.6% of the variance, as indicated by an R-Square of 0.5758 and an Adjusted R-Square of 0.5266. The model is statistically significant, with an F-statistic of 11.72 and a p-value below 0.0001, confirming that at least one predictor significantly impacts Salary. The fit statistics, including an Akaike's Information Criterion (AIC) of 2108.6748 and Schwarz's Bayesian Criterion (SBC) of 2172.9735, support this model as a viable predictive tool. However, the residual plot shows some variability around zero, suggesting potential issues and influential outliers. Although the model provides a reasonable fit, it may benefit from further refinement, such as addressing outliers or exploring interaction effects among predictors.

# (c) Fit a nonlinear regression with polynomial basis. Perform model check and report your findings.

SBC	2210.1033	C(p)	156.0000			

The nonlinear regression model with a polynomial basis was fitted to predict Salary using a polynomial degree of 2, allowing for quadratic relationships among the predictors. This model achieved an impressive R-Square of 0.9890 and an Adjusted R-Square of 0.9281, indicating that it explains approximately 99% of the variance in Salary, a significant improvement over the linear model. The F-statistic of 16.25 with a p-value of <0.0001 confirms the overall significance of the model.

However, while the high R-Square suggests a strong fit, the residual plot shows some patterns and larger residuals at the extremes, potentially indicating overfitting or sensitivity to certain observations. The model's fit statistics, such as the Akaike Information Criterion (AIC) of 1708.5733 and Schwarz's Bayesian Criterion (SBC) of 2210.1033, should be compared with the linear model's values to determine if the complexity of this model is justified. Overall, although the nonlinear model captures more variance in Salary, the residual patterns suggest that the model might be overly complex, which could affect its generalizability to new data.

#### (d) Compare the average squared error of all regression models on the validation set.

#### For each model, explore different options in the Property panel. What's your best model?

In comparing the linear and nonlinear regression models, the linear regression model (Reg) outperforms the polynomial regression model (Reg2) based on validation set metrics. The Validation Average Squared Error (ASE) for the linear model is 147,621.58, significantly lower than the 1,583,283.17 ASE for the polynomial model. Similarly, the Validation Root Mean Square Error (RMSE) for the linear model is 384.22, compared to 1,258.29 for the polynomial model. These metrics indicate that the linear model

provides more accurate predictions for Salary on the validation set. Adjustments could potentially improve model performance, such as using variable selection methods or experimenting with interaction terms in the linear model, or lowering the polynomial degree in the nonlinear model to reduce overfitting. However, based on the current results, the linear regression model is the best option, balancing simplicity and accuracy without the overfitting observed in the polynomial model.
